...Article on Maleriraptor Kuttyi...

In May 2025, scientists shared some exciting news—they found a brand-new dinosaur called *Maleriraptor kuttyi*. This dinosaur lived around 220 million years ago in what is now Telangana, India. The bones were actually found in the 1980s near a village called Annaram, but only now did experts realize it was a totally new kind of dinosaur. *Maleriraptor* was a small, fast meat-eating dinosaur, about six feet long, and walked on two legs. It's special because it's the first dinosaur of its type (called a *herrerasaur*) ever found in India. This shows that India had its own raptor-like hunters a long time ago.

For all of us at Indo Public School, this discovery is super exciting! It proves that amazing science can happen right here in our country. Scientists say *Maleriraptor* even lived through a big extinction event that killed many other dinosaurs, which means it was very strong and smart. Learning about this dinosaur feels like going on a fun science journey. Maybe one day, a student from our school will become a scientist and discover a dinosaur too! This story reminds us to stay curious—there's still so much to explore and find in our world.
